Assignment No. 5

Problem Statement: Implement the K-Means clustering algorithm using Python to analyze and visualize a given dataset.

Objective:

1. Understand and implement the K-Means clustering algorithm.
2. Apply K-Means to a dataset and analyze the results.
3. Use the Elbow Method to determine the optimal number of clusters.
4. Visualize clusters and interpret results.

Prerequisite :

1. A Python environment with essential libraries like pandas, numpy, matplotlib, seaborn, and scikit-learn.
2. Basic knowledge of Python, statistics, and machine learning principles.
3. Statistics: Understanding of mean, variance, and standard deviation.
4. Machine Learning: Basics of unsupervised learning, clustering, and K-Means.

Theory :

K-Means Clustering **is** an unsupervised machine learning algorithm used for partitioning a dataset into K distinct, non-overlapping clusters**.** It aims to group similar data points together while ensuring that different clusters are as distinct as possible.

Key Properties of K-Means:

1. **Unsupervised learning**: No labeled data is required.
2. **Centroid-based**: Each cluster is represented by its centroid (mean of the points).
3. **Iterative algorithm**: Repeatedly assigns data points and updates centroids.
4. **Works well with large datasets**: Faster than hierarchical clustering.

Working of K-Means Algorithm

Step 1: Choose K (Number of Clusters)

- Decide the number of clusters KKK manually or using methods like the **Elbow Method** or **Silhouette Score**.

Step 2: Initialize Centroids

- Randomly select **K data points** as the initial **cluster centroids**.

Step 3: Assign Each Data Point to the Nearest Centroid

- Compute the **Euclidean distance** between each data point and the centroids:

$$d(x, c) = \sqrt{\sum (x_i - c_i)^2}$$

- Assign each data point to the **closest centroid**.
- This step **forms K clusters**.

Step 4: Compute New Centroids

- For each cluster, calculate the **new centroid** by taking the **mean of all points** assigned to it:

$$C_j = \frac{1}{N_j} \sum_{i=1}^{N_j} x_i$$

where:

- Cj = New centroid of cluster j
- Nj = Number of points in cluster j
- xi = Data points in cluster j

Step 5: Repeat Until Convergence

- **Reassign points** to the new centroids.
- **Recalculate centroids**.
- Repeat **until centroids no longer change** (or changes are minimal).

3. Understanding WCSS (Within-Cluster Sum of Squares)

The **WCSS (Within-Cluster Sum of Squares)** measures how well data points fit within a cluster. It is used in the **Elbow Method** to find the optimal number of clusters.

Formula for WCSS:

$$WCSS = \sum_{j=1}^{K} \sum_{i=1}^{N_j} (x_i - C_j)^2$$

where:

- K= Number of clusters,
- Nj = Number of points in cluster j
- xi = Data points in cluster j
- Cj = Centroid of cluster

Interpreting WCSS

- **Lower WCSS** = Clusters are well-defined and compact.
- **Higher WCSS** = Clusters are too spread out (not well-defined).

4. The Elbow Method to Find Optimal K
The Elbow Method helps determine the best value of K by plotting **WCSS vs. K**.

How to Use the Elbow Method?

1. Compute **WCSS for different values of K**.
2. Plot **WCSS vs. K**.
3. Find the **"elbow point"** where WCSS stops decreasing sharply.
4. The corresponding **K is optimal**.

Why Does the Elbow Method Work?

- Adding more clusters **always decreases WCSS**.
- But after a certain **K**, **adding more clusters has little effect**.
- The **"elbow"** is where **WCSS reduction slows down significantly**.

5. Evaluation Metrics for K-Means
Silhouette Score

Measures how well a point fits within its cluster:

$$S = \frac{b - a}{\max(a, b)}$$

where:

- a = Average distance to other points in the same cluster.
- b = Average distance to points in the nearest cluster.

Interpretation:

- **S ≈ 1:** Well-clustered
- **S ≈ 0:** Overlapping clusters
- **S ≈ -1:** Wrong clustering

Code & Output

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
from sklearn.cluster import KMeans
from sklearn.preprocessing import StandardScaler
from sklearn.metrics import silhouette_score
from sklearn.impute import SimpleImputer
from sklearn.decomposition import PCA
```

```
from sklearn.datasets import load_wine
# Load Wine dataset
wine = load_wine()
df = pd.DataFrame(wine.data, columns=wine.feature_names)

# Display first few rows
print(df.head())

Conclusion:

In this assignment, we implemented **K-Means clustering** and **KNN classification** on the **Wine dataset**. The **K-Means model** resulted in a **Silhouette Score of 0.285**, indicating weak cluster separation. The **KNN classifier achieved 72.2% accuracy**, with balanced precision, recall, and F1-score. However, the confusion matrix showed misclassifications, particularly in class 2.
